Our hackathon choices

We chose Problem 9 and Problem 11 because both solve a clear problem, can be demonstrated simply, and give us practical ways to check whether our solution works.

Problem 9 Medication Safety

The idea: A tool that checks a patient's medicine list and warns the doctor about possible problems, such as two medicines that should not be taken together.

How we would solve it: Use the medicine reference tables provided for the competition, identify the medicines, and show the most serious warnings first with a clear explanation. The doctor makes the final decision.

Why we chose it: The benefit is easy to understand, and we can test the warnings against the supplied references. The challenge is recognizing misspelled medicine names and avoiding unnecessary warnings.

Problem 11 Smart Data Masking

The idea: A tool that hides sensitive customer information from people who do not need to see it. For example, support staff might see only part of a card number.

How we would solve it: Automatically find sensitive details and show different views for different staff roles. We would demonstrate it on two databases without changing the original records.

Why we chose it: We can clearly show who is allowed to see what and test whether the restrictions work. The challenge is making sure hidden information cannot still be accessed another way.

Why we preferred these over the alternatives

Problem 7 — Discharge Care Plans: Useful, but simplifying and translating hospital instructions must preserve every medicine, dose and date. We prefer Problem 9 because reference-based checks give us a more direct way to verify many results.

Problem 2 — Returns Fraud: Also useful, but deciding whether a customer complaint is genuine involves uncertain patterns and the risk of wrongly accusing someone. We prefer the more clearly defined checks in Problems 9 and 11.

What makes this a good plan

We can focus on a small working solution, test it carefully, and explain it clearly. Neither problem is easy or a guaranteed winner. Our aim is to show reliable results and a convincing demonstration rather than attempt too many features.
